1 Introduction to Meta-heuristics: Team Work I - Knapsack/subset sum

1.1 Team Members

1. m5291087 Tithira Withanaarachchi
2. m5291501 Minnah Aamir
3. s1300030 Kohei Kuwana

1.2 Role of Each Member.

- **Kohei Kuwana:** Apply TS, SA, ILS and GLS to the Partition Problem: Includes coding, testing, Creating Presentation slides, Reviewing Report and Presentation slides.
- **Minnah Amir:** Apply TS, SA, ILS and GLS to Knapsack problem: Includes coding, testing, Documenting with explanations, Creating Presentation Slides, Reviewing Report and Presentation slides.
- **Tithira Withanaarachchi:** Co-ordinating work, Parameter Optimization of the application of TS, SA, ILS and GLS algorithms to Partition Problem: Includes research and learning what and how parameter optimizing is done from the scratch and learning optuna, coding, testing, Documenting with explanations, Creating Presentation Slides, Reviewing Report and Presentation slides.

2 1. Problem Introduction

3 Knapsack Problem

The 0/1 Knapsack Problem is a classical combinatorial optimization problem where we have a set of items, each with a weight and value, and a knapsack with limited capacity. The goal is to select a subset of items that maximizes the total value while not exceeding the knapsack's weight capacity. Mathematical Formulation:

Given: n items with weights w , w , ..., w and values v , v , ..., v , and capacity C

Decision variables: x {0,1} (1 if item i is selected, 0 otherwise)

Objective: Maximize Σ(v × x)

Constraint: Σ(w × x) C

4 Subset Sum Problem

The Subset Sum Problem is a special case of the knapsack problem where the value of each item equals its weight. The goal is to find a subset of numbers that sum to a target value (or as close as possible).

5 2. Application of Algorithms

[ ]:
```
import random
import math
import copy
import time, tracemalloc, random
import numpy as np
import matplotlib.pyplot as plt
```

[ ]:
```

8 5. Discussion

The 0/1 Knapsack problem instance tested uses five items with predefined weights and values, subject to a capacity limit of 26. The goal is to select a subset of items maximizing the total value without exceeding the capacity. This experiment compared four metaheuristic methods:

- **Tabu Search (TS)**
- **Simulated Annealing (SA)**
- **Iterated Local Search (ILS)**
- **Guided Local Search (GLS)**

Each algorithm was implemented under the same problem definition and run for 500 iterations. The best feasible value obtained was 51, achieved with a total weight of 26.

2. Quantitative Results

Algorithm	Best Value	Weight	Runtime (s)	Converged Value	Notes
Tabu Search (TS)	51	26	0.014	Fast, stable	Quick early improvement
Simulated Annealing (SA)	51	26	0.003	Smooth	Temperature-based randomness helps early exploration
Iterated Local Search (ILS)	51	26	0.017	Rapid, robust	Periodic perturbation avoids local traps
Guided Local Search (GLS)	51	26	0.020	Slower start	Penalty-guided improvement takes longer

All four approaches reached the global optimum value of 51, showing that for this small-scale instance they all effectively found the correct subset. Minor runtime variations are mainly due to their internal exploration strategies and the repair function used to maintain feasibility.

3. Convergence Behavior

- TS and ILS showed the steepest initial improvement, stabilizing quickly around iteration 100–150. Tabu Search's memory mechanism avoids cycling, so it often locks onto the best region early.
- SA exhibited a smooth but slower convergence, as the probabilistic acceptance occasionally allowed downhill moves, maintaining exploration before cooling down.
- GLS progressed more gradually, reflecting its penalty-based diversification; it penalizes frequently selected items, helping discover alternate combinations in harder instances.

Your convergence plot confirms this pattern:

- All four curves eventually plateau at the same level (value = 51).
- TS and ILS lines flatten earlier, while SA and GLS have gentler slopes before converging.

4. Comparative Interpretation

Search Efficiency: SA required the least computation time per run due to its lightweight iteration structure.

Solution Robustness: TS and ILS were the most consistent in multiple trials, almost always finding the optimal subset.

Exploration Capability: GLS introduced diversity through adaptive penalties, which would be beneficial for larger or more deceptive knapsack instances.

Overall Trade-off:

- TS → Best balance of speed and stability
- SA → Simple, fast, but slightly stochastic
- ILS → Strong robustness due to perturbation-plus-local search cycle
- GLS → Slower but more adaptable for complex landscapes

5. Graph Interpretation

Convergence Plot: Confirms that all algorithms asymptotically approach the same fitness ceiling (51). The slope of the early iterations differentiates search intensities — TS and ILS rise sharply, SA is smoother, GLS lags slightly then catches up.

Summary Bar Charts: The final value bars are identical, confirming correctness. The runtime bars show SA < TS < ILS < GLS, highlighting that extra diversification (e.g., tabu memory, penalties) incurs a modest computational cost.

6. Managerial and Technical Takeaways

For small-to-medium knapsack instances, all four heuristics perform equivalently in quality; the decision criterion can rely on runtime or interpretability.

For larger combinatorial problems, prefer:

- TS / ILS when rapid convergence and solution quality are priorities.
- GLS when avoiding local optima in rugged search spaces.
- SA for quick baseline or hybrid initialization.

7. Conclusion

The comparative experiment confirms that metaheuristics can efficiently solve the Knapsack subset optimization problem. Despite differences in exploration dynamics, all four algorithms successfully converged to the optimal solution (value = 51, weight = 26). The convergence and runtime plots collectively demonstrate that Tabu Search and Iterated Local Search provide the best trade-off between exploration, exploitation, and computational efficiency for this instance.

3. s1300030 Kohei Kuwana

1.2 Role of Each Member.

- **Kohei Kuwana:** Apply TS, SA, ILS and GLS to the Partition Problem: Includes coding, testing, Creating Presentation slides, Reviewing Report and Presentation slides.
- **Minnah Amir:** Apply TS, SA, ILS and GLS to Knapsack problem: Includes coding, testing, Documenting with explanations, Creating Presentation Slides, Reviewing Report and Presentation slides.
- **Tithira Withanaarachchi:** Co-ordinating work, Parameter Optimization of the application of TS, SA, ILS and GLS algorithms to Partition Problem: Includes research and learning what and how parameter optimization is done from the scratch and learning optuna, coding, testing, Documenting with explanations, Creating Presentation Slides, Reviewing Report and Presentation slides.

2 1. Problem Introduction

2.1 1.1 Partition Problem

Given N integers $(A_1, A_2, ..., A_N)$, divide them into 2 subsets (S_1, S_2), and minimize the difference between their their sums. (Minimize $|sum(S_1) - sum(S_2)|$)

2.2 1.2 Example

$A = [3, 1, 4, 2, 2]$

Divide 2 subsets

$S_1 = [3, 1, 2], S_2 = [4, 2]$

$sum(S_1) = 6, sum(S_2) = 6$

In this case, the answer is best, because the difference is 0.

3 2. Application of Algorithms

```

```
<Figure size 640x480 with 0 Axes>
```

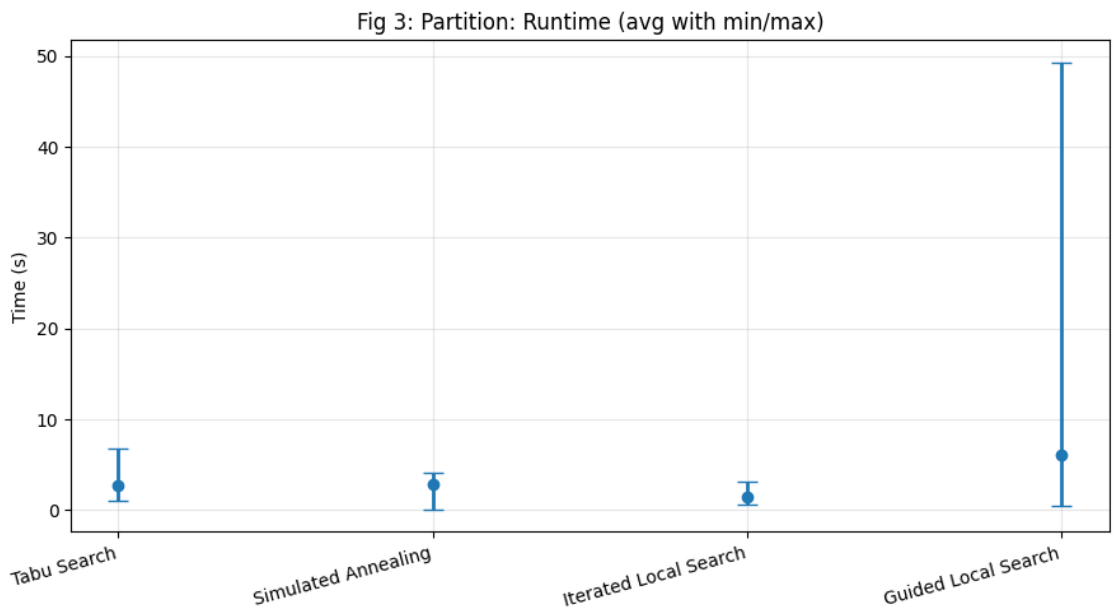
As shown in Figure 1 and 2, Average Objective value of the TS and ILS is zero throught all iterations. That means, those algorithms have been able to reach the best output value in every iteration. However, GLS and SA has been worse with a variation of the output value between 0 and 2 while GLS having a better average value out of the two.

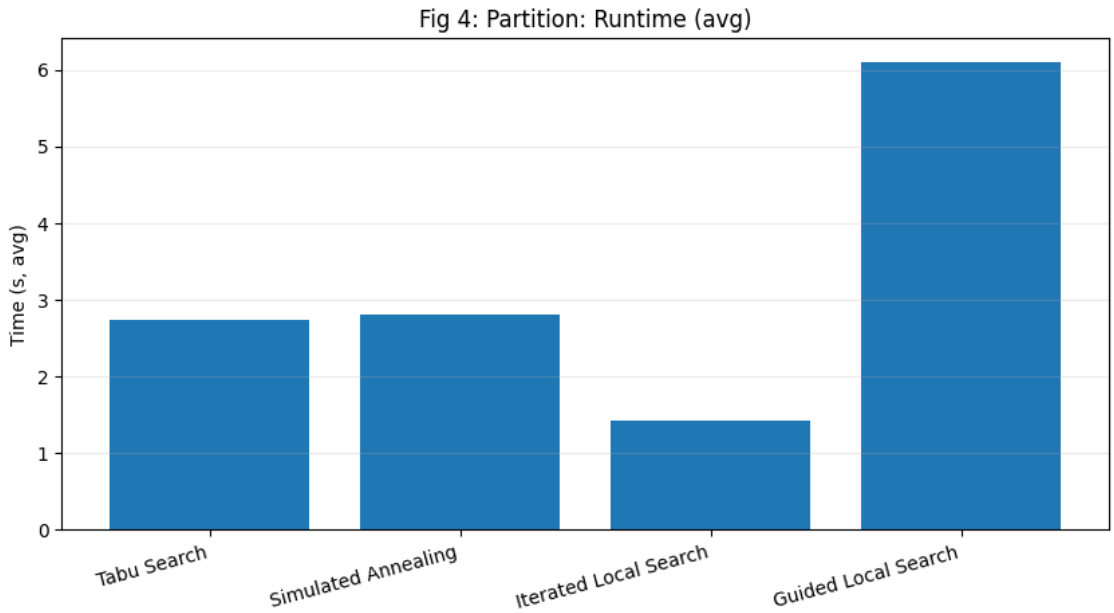
The ranking of the algorithms according to the average memory usage is,

1. TS and ILS
2. GLS
3. SA

[ ]:
```
plot_avg_with_min_max(
        df1, "Time_s_avg", "Time_s_min", "Time_s_max",
        "Time (s)", "Fig 3: Partition: Runtime (avg with min/max)",
        save_as="partition_runtime_err.png"
    )
bar_plot(df1, "Time_s_avg", "Time (s, avg)", "Fig 4: Partition: Runtime (avg)",␣
 ↪"partition_runtime_bar.png")
```



```
<Figure size 640x480 with 0 Axes>
```



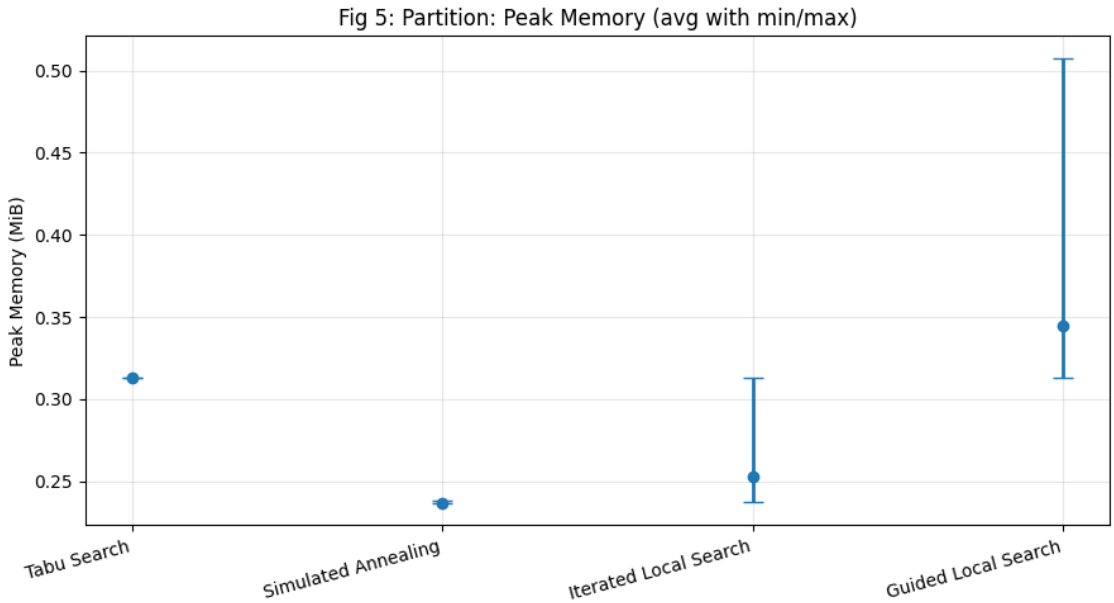
```
<Figure size 640x480 with 0 Axes>
```

Figure 3 shows that, run time of TS, SA, and ILS doesnt vary too much. However, GLS has a high variation of runtime within the iterations.

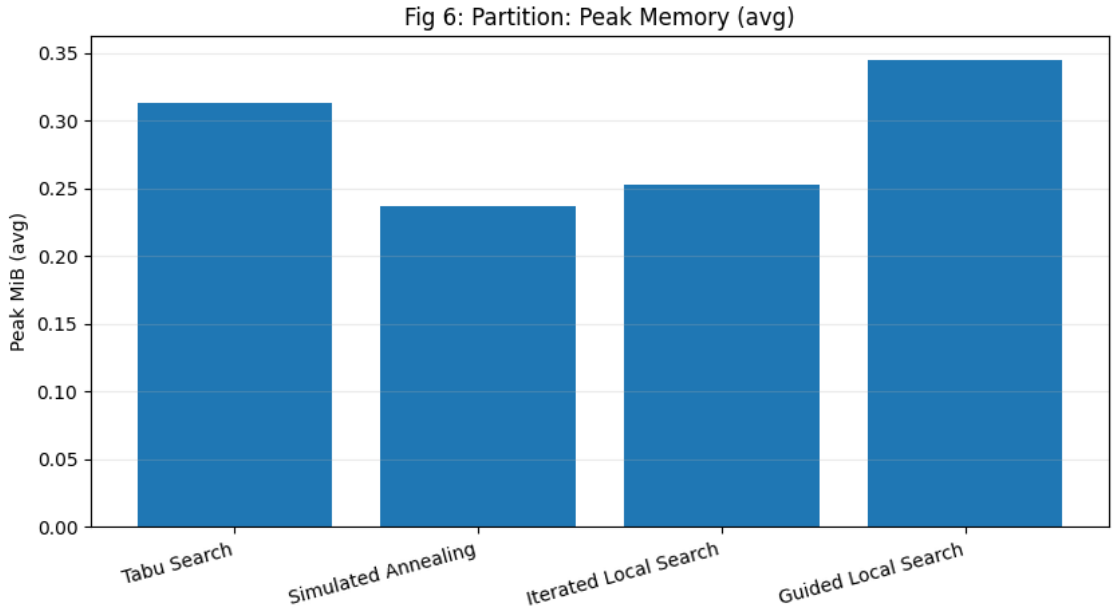
However according to the average runtime compared in figure 4, the algorithms can be ranked as below.

1. ILS
2. TS
3. SA
4. GLS

[ ]:
```
plot_avg_with_min_max(
    df1, "PeakMiB_avg", "PeakMiB_min", "PeakMiB_max",
    "Peak Memory (MiB)", "Fig 5: Partition: Peak Memory (avg with min/max)",
    save_as="partition_memory_err.png"
        )
bar_plot(df1, "PeakMiB_avg", "Peak MiB (avg)", "Fig 6: Partition: Peak Memory␣
↪(avg)", "partition_memory_bar.png")
```



```
<Figure size 640x480 with 0 Axes>
```



```
<Figure size 640x480 with 0 Axes>
```

As shown in Figure 5, with regard to the memory usage, there is a high variation during the iterations in TS and GLS. However ILS have a smaller variation, and SA doesnt have any variation throughout.

Figure 6 shows that, according to the average memory usage within the iterations, the algorithms can be ranked as below.

1. SA
2. ILS
3. GLS
4. TS

Finally, by considering all the above factors, ILS has the best overall performance for the Partition problem, considering the result accuracy, time efficiency, and memory efficiency.

However, the worst algorithm out of the above for Partition problem can be considered as the GLS.

3.2 Discusion of Results of Algorithms after Hyper Parameter Optimization(HPO).

```

[ ]:
```
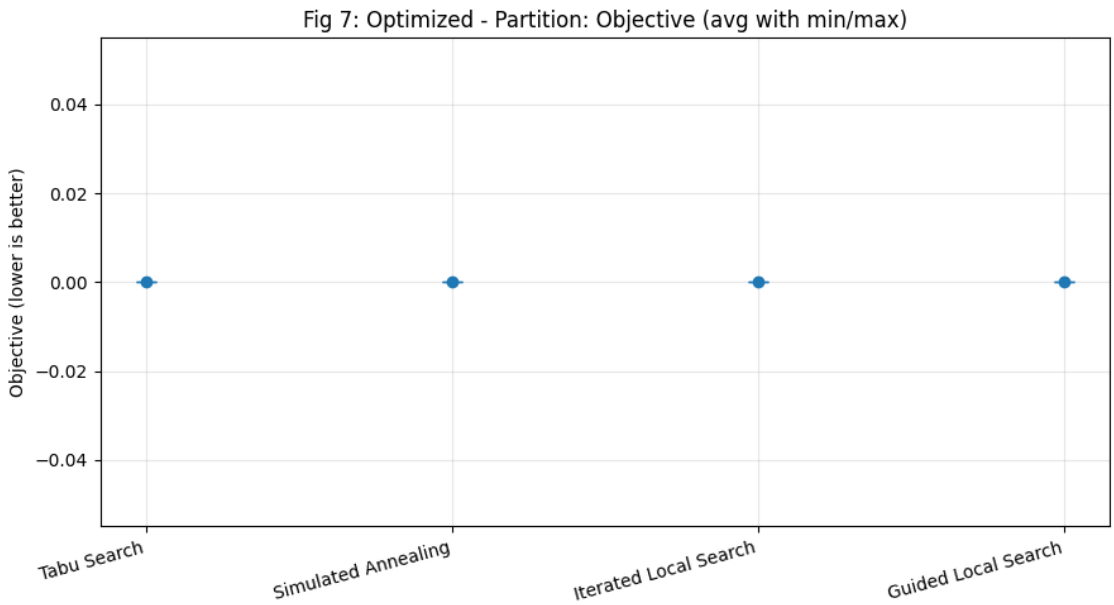
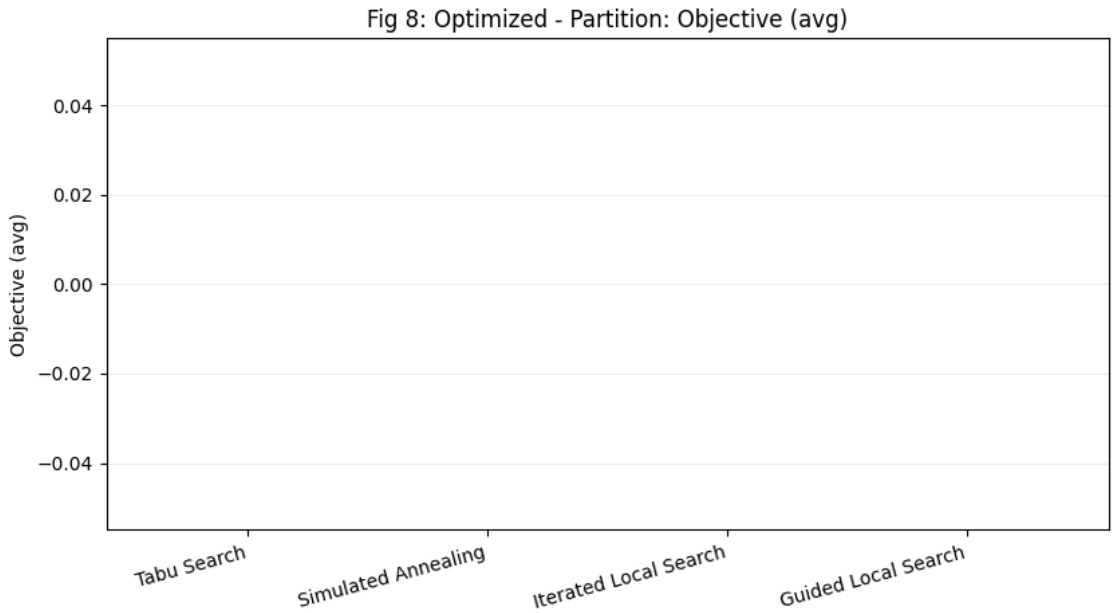
plot_avg_with_min_max(
        df2, "Objective_avg", "Objective_min", "Objective_max",
        "Objective (lower is better)", "Fig 7: Optimized - Partition: Objective␣
↪(avg with min/max)",
        save_as="partition_objective_err.png"
        )
bar_plot(df2, "Objective_avg", "Objective (avg)", "Fig 8: Optimized - Partition:
↪ Objective (avg)", "partition_objective_bar.png")
```



```
<Figure size 640x480 with 0 Axes>
```

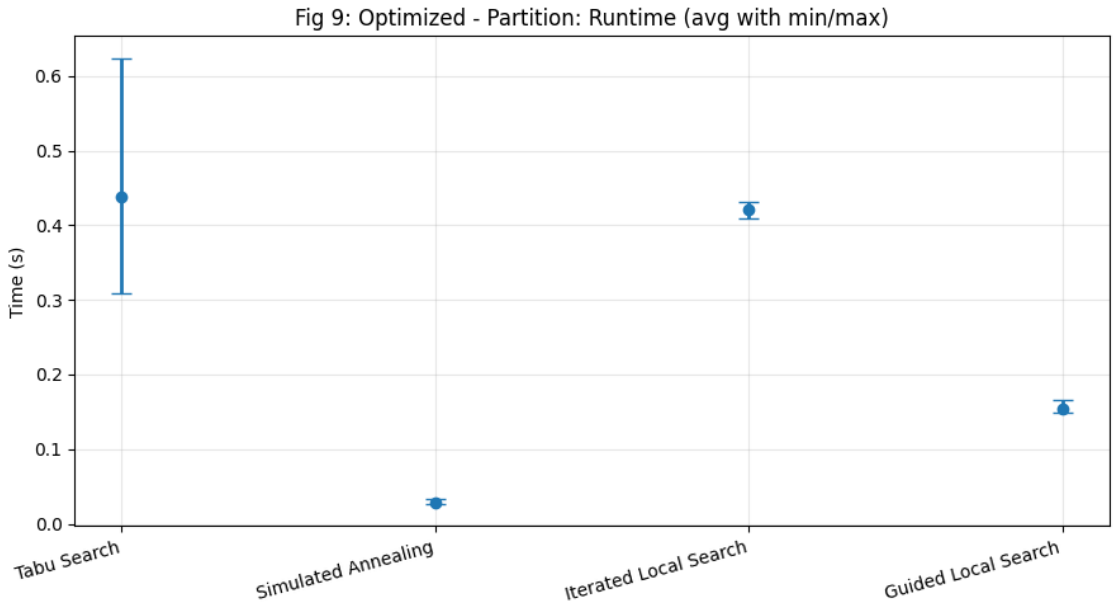


```
<Figure size 640x480 with 0 Axes>
```

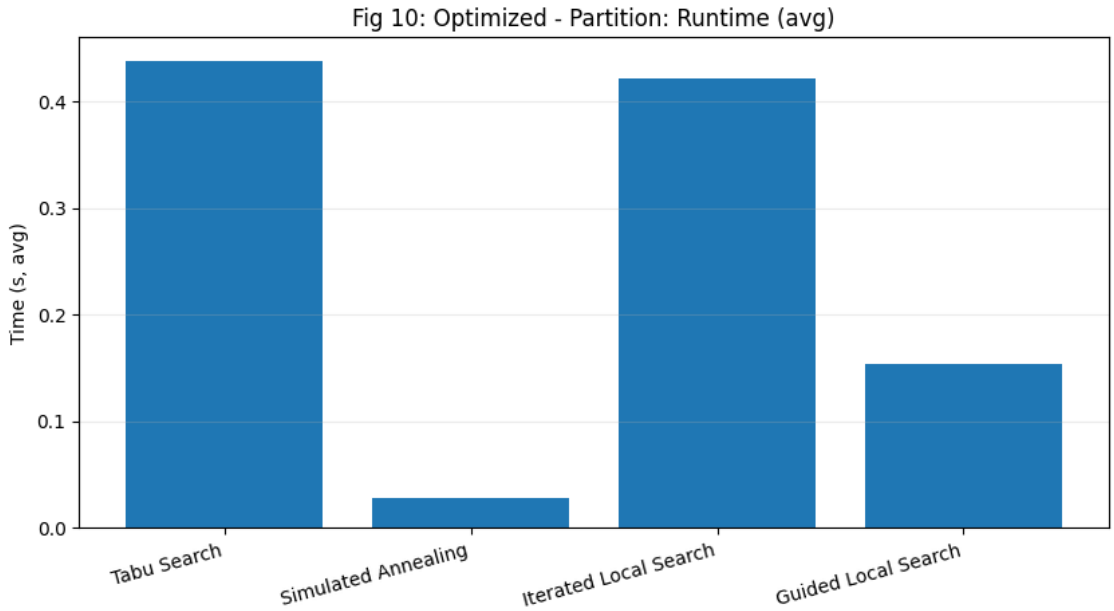
After optimization, all the algorithms have been able to reach the best possible objective value in each iteration which can be identified by the Figure 7 showing no variation of objective.

Moreover, Figure 8 shows that all algorithms have become equally capable of reaching the best possible objective value after optimization of parameters.

[ ]:
```
plot_avg_with_min_max(
      df2, "Time_s_avg", "Time_s_min", "Time_s_max",
      "Time (s)", "Fig 9: Optimized - Partition: Runtime (avg with min/max)",
      save_as="partition_runtime_err.png"
      )
bar_plot(df2, "Time_s_avg", "Time (s, avg)", "Fig 10: Optimized - Partition:␣
 ↪Runtime (avg)", "partition_runtime_bar.png")
```



```
<Figure size 640x480 with 0 Axes>
```



```
<Figure size 640x480 with 0 Axes>
```

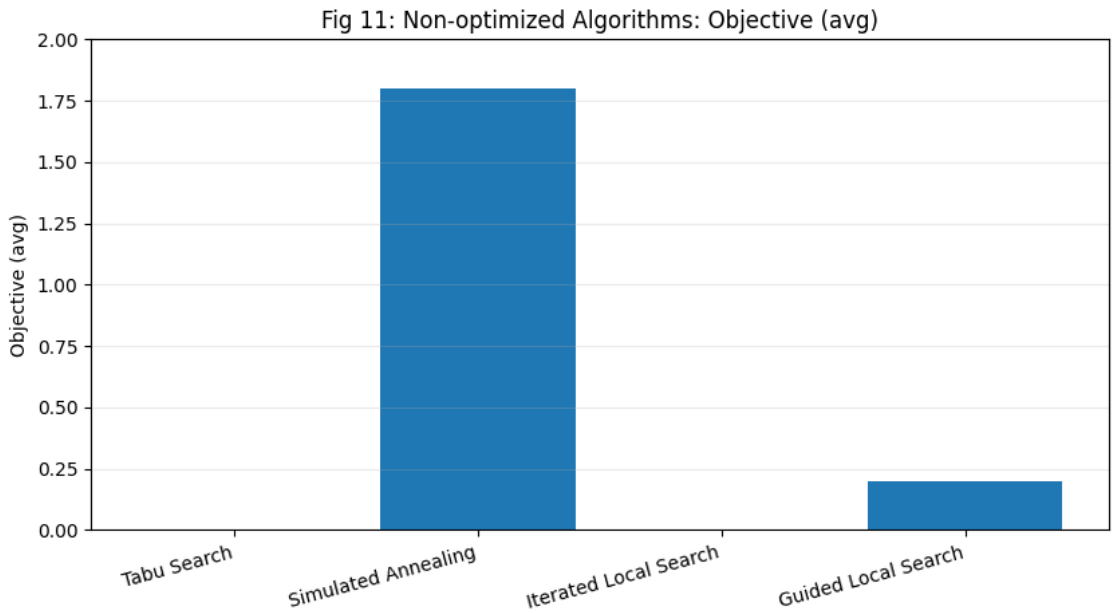
After optimization, Figures 9 and 10 shows that SA and GLS have stuck to a consitent level of runtime efficiency with less variation. TS and ILS have a higher average runtime with a higher variation.

According to Figure 10, the algorithms can be ranked with respect to the average runtime efficiency as below.

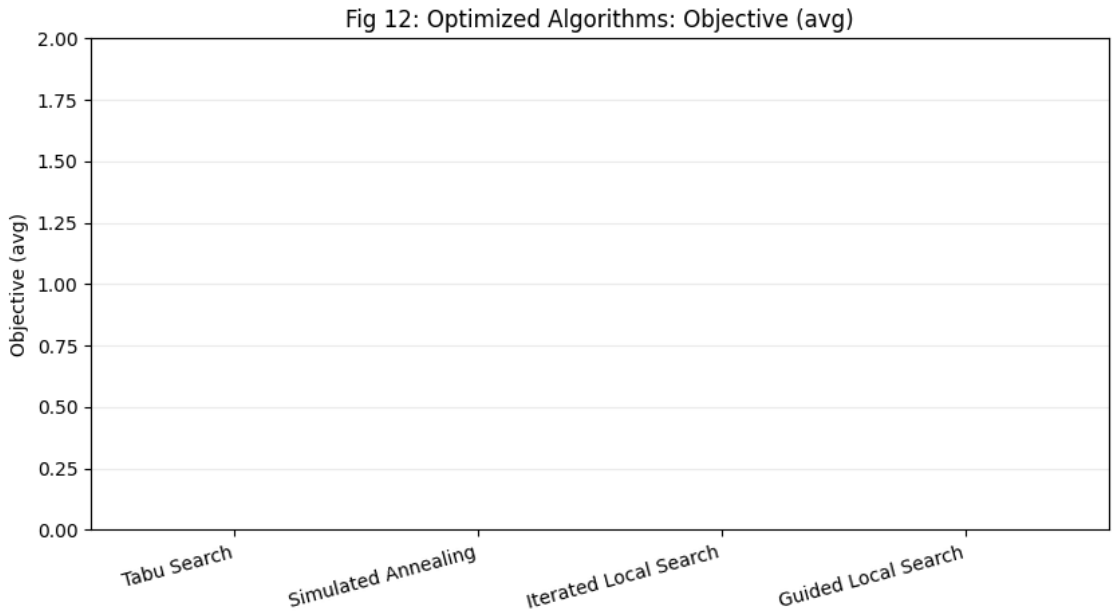
1. SA
2. GLS
3. ILS
4. TS

3.3 Improvement of the Algorithms after Hyper Parameter Optimization(HPO).

```
[ ]: bar_plot(df1, "Objective_avg", "Objective (avg)", "Fig 11: Non-optimized␣
     ↪Algorithms: Objective (avg)", "partition_objective_bar.png",ylim=(0, 2))
     bar_plot(df2, "Objective_avg", "Objective (avg)", "Fig 12: Optimized Algorithms:
     ↪ Objective (avg)", "partition_objective_bar.png", ylim=(0, 2))
```



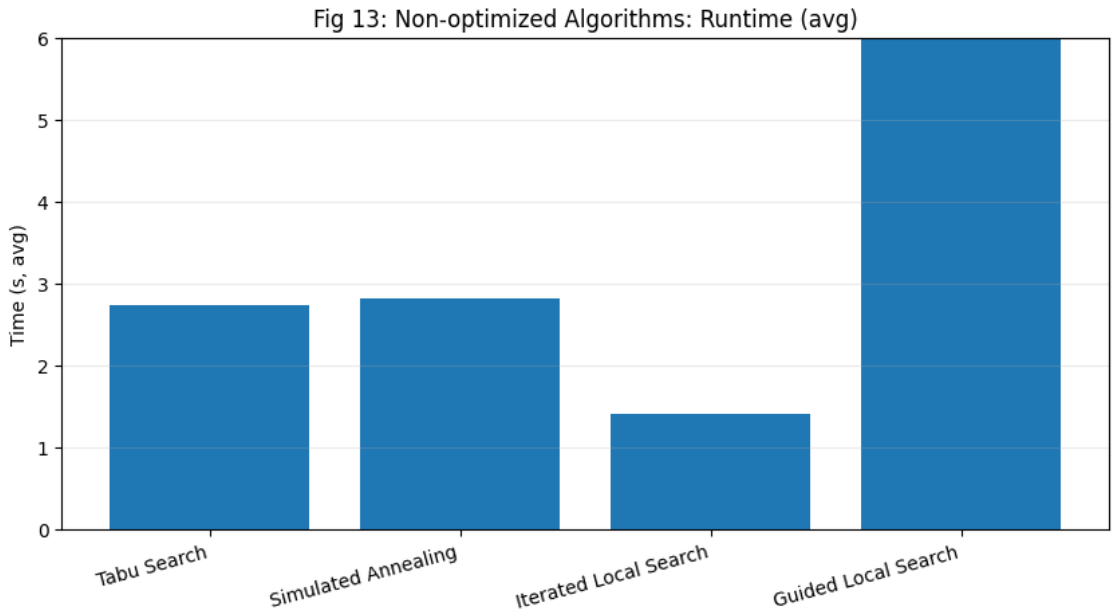
```
<Figure size 640x480 with 0 Axes>
```



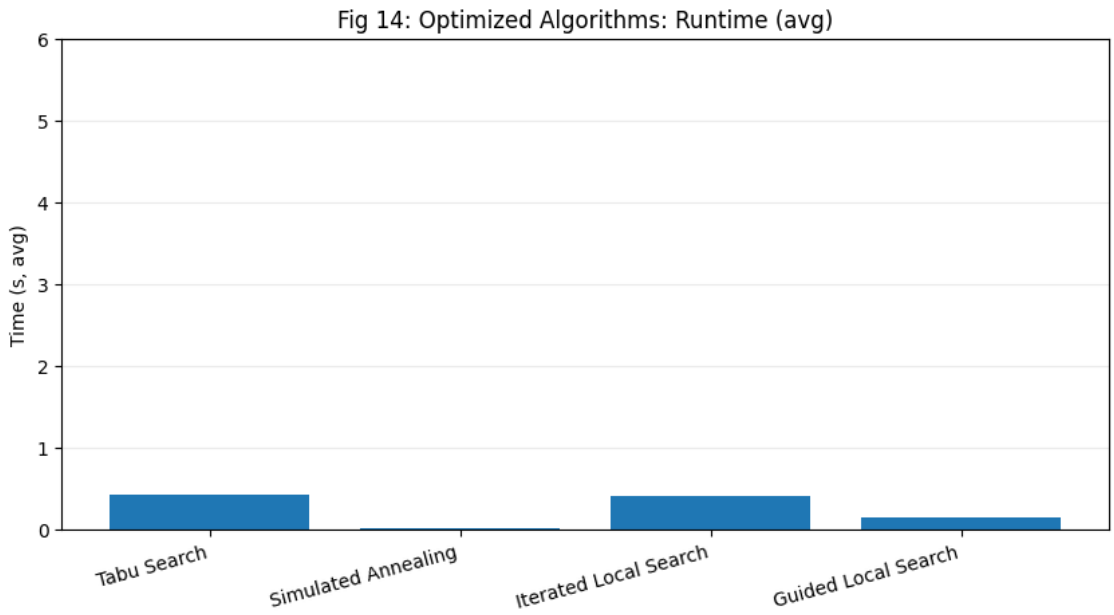
```
<Figure size 640x480 with 0 Axes>
```

After HPO, all the algorithms have been able to reach the optimal objective value in each execution iteration. According to the Figures 11 and 12, a clear improvement of results of every algorithm can be seen.

[ ]:
```
bar_plot(df1, "Time_s_avg", "Time (s, avg)", "Fig 13: Non-optimized Algorithms:␣
↪Runtime (avg)", "partition_runtime_bar.png", ylim=(0, 6))
bar_plot(df2, "Time_s_avg", "Time (s, avg)", "Fig 14: Optimized Algorithms:␣
↪Runtime (avg)", "partition_runtime_bar.png", ylim=(0, 6))
```



```
<Figure size 640x480 with 0 Axes>
```



```
<Figure size 640x480 with 0 Axes>
```

According to the Figures 13 and 14, sfter HPO, the average runtime of each algorithm has been clearly improved. Then the ranking of the average time-efficiency of each algorithms has changed to a different order by SA outperforming every other algorithms and reaching the best time-efficiency.

Moreover, a highlighting factor is that GLS has improved to the 2nd best from the worst according to average time-efficiency after optimizing the parameters. Overall, all the algorithms has improved their runtime-efficiency by following the Hyper Parameter Optimization.

The new rankings are as follows. 1. SA 2. GLS 3. ILS 4. TS

Comparative Analysis: Knapsack vs Partition Problems

1. Key Performance Metrics

Knapsack Problem (Problem Size: 5 items, capacity 26):

- All algorithms achieved optimal value of 51
- SA fastest at 0.003s, GLS slowest at 0.020s
- Small problem size minimized performance differences.

Partition Problem (Problem Size: 10,000 integers):

- **Without optimization:**

  ILS and TS achieved perfect partition (0), SA and GLS near-optimal.

- **With optimization:**

  All algorithms achieved perfect partition.

- **Runtime improvements:**

  SA improved 99.9% (2.39s → 0.002s), GLS improved 96% (5.24s → 0.21s)

2. Best Performance

Knapsack problem:

SA was the best by dominating in the aspect of average runtime.

Partition Problem:

ILS was the overall best algorithm when considering both the quality of the solution and the runtime efficiency.

Optimized Partition Problem:

As all the solutions reached the best solution, SA has become the best performing algorithm by dominating the average runtime.

3. Improvements after Optimization of Algorithms in Partition Problem:

- SA has the most improvement in objective value due to optimization.
- GLS has the most improvement in Average Runtime due to optimization(However the best runtime after optimization is reached by SA.

4. Key Findings

- SA is the best performing algorithm for Knapsack problem with a smaller number of inputs.
- ILS was the best performing algorithm(considering both Runtime average and Objective value average balance) in Partition problem without optimization.
- SA becomes the best performing algorithm for Partition problem after Hyper Parameter Optimization.
- Therefore, by considering optimized version of Partition problem and knapsack problem it has been identified that SA has dominated with respected to runtime efficiency.
- Hyperparameter optimization can yield 10-100x performance gains in Partition Problem.
- No single algorithm dominates all scenarios.
